equilibrium of chromosome 2 in

German families with schizophrenia.

1. Evidence from family studies points to a significant role for genetic factors in the etiology of schizophrenia. Since linkage studies, using a variety of genetic markers, have yielded conflicting results, we examined whether linkage to schizophrenia might be restricted to a specific part of the genome. 2. Markers highly

associated with gene frequency in the population could be identified on the centromeric side of the D2 dopamine receptor gene on chromosome 2. 3. We performed a linkage study of all families typed at D2 loci and found a statistically significant linkage signal (P less than 0.01) for the marker D2S102. This locus could be excluded for schizophrenia by the binomial test with a 95% confidence level. 4. The haplotype linked to the schizophrenia risk locus was closely associated with a polymorphism in the repeat (Y)1.2 element in the D2S102 flanking region, located on the centromeric side

of the D2 gene. 5. The two polymorphisms, present at the risk and non-risk allele, respectively, are in strong linkage disequilibrium with each other. /* * Copyright (C
