this phenomenon may explain why weld joints fail during service in the field. while there is no doubt that thermo-mechanical fatigue causes crack growth, there is a paucity of data available to assess the role of residual stresses. this is despite the clear and obvious importance of residual stresses in dictating crack growth rates. in this paper, we report the fabrication and analysis of an integrated sensing device capable of measuring the input voltage  $v$ , current  $i$ , and switching on and off-time  $t_1$  during transient power pulse. the integrated sensing device on a universal serial bus (usb) port is constructed by a controller chip, a resistor, a capacitor, and an amplifier. the output signals of the integrated sensing device are sent to the national instruments data acquisition system (daq) via the usb port. to analyze the power pulse, we put the power pulse of different duty cycle and pulse width on the in-line current sensor signal. the result showed that the rising time, steady time, and falling time of a pulse power are affected by the pulse width. in this study, we used the pulse width ranging from 2, 5, 7, 9, 15, to 20 ms to detect the input voltage, output current of the positive pulse waveform. furthermore, the input voltage, output current of the negative pulse waveform are tested as well. finally, we get the  $i$ - $v$  curve for the power pulse and compare the results of 2 sets of experiments. it can be found that the charging and discharging time in direct current and power pulses are consistent. erda, 2015. d. goodman and a. h. gunawan, fabrication of sustainable pipeline-like composite slabs using combined adhesive mortar mixtures with or without snowcrete, applied geochemistry., 44, 17-23, 2015. abstract. hazardous waste, or contaminated effluent, is often deposited in riverbeds, and near the landfill, or near the landfills. after being out of the landfill, or being dumped near the landfill, the hazardous waste, or contaminated effluent, will pollute the river and be drained into the river. in order to prevent that, the riverbed will be cracked and broken by the disposal of hazardous waste, or contaminated effluent, and the river will be polluted by it. therefore, the hazardous waste, or contaminated effluent, disposal near the landfill, or near the landfill will become one of the major causes of riverbed cracking and breaking.

for example, the sudden formation of the kink band could be imaged using stimulated-emission depletion (sted) microscopy, or possibly the band could be etched away at the crack site using optical excitation with low-power lasers. on a global level, the tendency to sinkage has been found to be more frequent in areas with fine-grained, stiff soils, most often in high rainfall regions. the increased soil stiffness and substantial matric potential are two factors that lead to a greater potential for a negative influence of rainfall on aquifer conditions. through analysis of the natural water stored in the geological media, a greater amount of water is retained, which can lead to increased levels of water pressure or drawdown within the aquifer. this in turn can result in the shrinkage and loosening of soil in the region, leading to a condition called soil instability. bones and other deformed, sheared fossils that are found in these wells tend to occur at specific intervals in the sediments that line the hollows and fissures. some systems can show an incongruence in the angular deviation of the fractures. microscopy indicates that the mudstones surrounding the formations that are responsible for the elongation are compactly laminated. these mudstones are often referred to as shale. the principal factors that cause subsidence are related to plate tectonics and the load that the earth's crust must sustain. if the crust experiences unequal flexural loads, this flexural mismatch may generate stress gradients within the mantle, and these stresses can transmit to the earth's surface. as the crust moves it is under tensile stress in the upper mantle, and in several locations, it is under compressive stress in the lower mantle. as the moving crust sinks into the mantle, the high-pressure region surrounding the sinking zone forces a more densely mineralized zone to flow towards the low-pressure region, similar to a submarine volcano. 5ec8ef588b
